# 1 Day 1: April 6

Grade: solve 2~4 exercises (report)

Throughout this lecture,

- we work over  $\mathbb{C}$ .
- A projective scheme is a projective scheme over  $\mathbb{C}$ , i.e. a closed subscheme of  $\mathbb{P}_{\mathbb{C}}^N$  for some  $N$ .
- A variety is an integral scheme which is separated and of finite type over  $\mathbb{C}$ .

**Definition 1.1.** A Fano variety is a smooth projective variety  $X$  such that  $-K_X$  is ample.

**Definition 1.2.** Let  $X$  be a smooth variety. A canonical divisor  $K_X$  is a Weil divisor such that  $\mathcal{O}_X(K_X) \cong \omega_X := \bigwedge^{\dim X} \Omega_X^1 \in \text{Pic}(X)$ . ( $\Omega$  is a locally free sheaf of rank(=  $\dim X$ )) the canonical divisor

**Example 1.3.** If  $X$  is a smooth projective curve, then  $X$  is Fano iff  $X \cong \mathbb{P}^1$ .

*Proof.* 1. A divisor  $D$  on  $X$  is ample iff  $\deg D > 0$ . ( $\deg D = \sum a_i$  for  $D = \sum a_i P_i$ )

2.  $\deg K_X = 2g - 2$ , ( $g := h^1(X, \mathcal{O}_X) \in \mathbb{Z}_{2n}$ )

3.  $g = 0$  iff  $X = \mathbb{P}^1$ .

Moreover,  $\mathbb{P}^n$  is Fano. □

**Example 1.4.** Let  $X \subset \mathbb{P}^N$ : smooth hypersurface of  $\deg d$ . For example, we may consider  $X = \{x_0^d + \cdots + x_N^d\}$ . Then,  $X$  is Fano iff  $d \leq N$ .

*Proof.* (Sketch) By the adjunction formula,

$$\mathcal{O}_X(K_X) \cong \mathcal{O}_{\mathbb{P}^N}(K_{\mathbb{P}^N} + X)|_X \cong \mathcal{O}_{\mathbb{P}^N}(-N - 1 - d)|_X.$$

Then,  $\text{Pic } \mathbb{P}^N = \{\mathcal{O}_{\mathbb{P}^N}(m) | m \in \mathbb{Z}\} \cong \mathbb{Z}$  (group isomorphism). □

Why 3-folds? It is started by Gino Fano (1904~), and the following theorem gives a motivation:

**Theorem 1.5** (Lüroth, 1876).  $\mathbb{C} \subset K \subset \mathbb{C}(x)$  be field extensions. Assume the transcendental degree of  $K$  is one. Then,  $K \cong \mathbb{C}(y)$ .

The Lüroth problem states that: if  $\mathbb{C} \subset K \subset \mathbb{C}(x_1, \dots, x_n)$  field extensions, assuming the transcendental degree of  $K$  is  $n$ , then  $K \cong \mathbb{C}(y_1, \dots, y_n)$ ?

**Theorem 1.6** (Castelnuovo, 1886). The Lüroth problem is true if  $n = 2$ .

The idea of this theorem is to convert Lüroth problem into a geometric version. A field extension  $K \subset \mathbb{C}(x)$  corresponds to a dominant rational map  $\mathbb{P}_{\mathbb{C}}^1 \rightarrow X$ , and the transcendental degree one is equivalent to that  $X$  is curve. Here we may assume  $X$  to be a smooth projective curve. So, the Lüroth theorem can be restated as

**Theorem 1.7.** If  $\mathbb{P}_{\mathbb{C}}^1 \rightarrow X$  for a smooth projective curve  $X$ , then  $X \cong \mathbb{P}_{\mathbb{C}}^1$ .

For  $n = 2$ , we consider the rationality criterion.

**Theorem 1.8.** Let  $X$  be a smooth projective surface. Then,  $X$  is rational iff  $H^1(X, \mathcal{O}_X) = H^0(X, 2K_X) = 0$

**Example 1.9.** If a surface  $X$  is del Pezzo(=Fano surface), then  $X$  is rational. It is because if  $-K_X$  is ample then  $H^0(X, 2K_X) = 0$  ( $\because$  if not, then  $2K_X$  is linearly equivalent to an effective divisor  $D$ , and  $2(-K_X)^2 = 2K_X \cdot K_X = D \cdot K_X = \sum a_i C_i \cdot K_X \geq 0$ .) Also, by the Kodaira vanishing, we have  $H^1(X, \mathcal{O}_X) = H^1(X, \mathcal{O}_X(K_X + (-K_X))) = 0$ .

How about  $n = 3$ ? We may consider

- Three-dimensional rationality criterion?
- Fano hypersurface  $X \subset \mathbb{P}^4$  are rational?

To settle the second question, Fano studied similar and easier Fano threefolds.

**Theorem 1.10.** *There is a counterexample to Lüroth's problem. Specifically, if  $X$  is the complete intersection of deg 2 hypersurface and deg 3 hypersurface in  $\mathbb{P}^5$ ,  $X$  is not rational (1908, Fano), but  $X$  is unirational (1912, Enriques).*

**Theorem 1.11** (1942, G. Fano). *There is a hypersurface of degree 3  $X \subset \mathbb{P}^4$  which is not rational but unirational.*

*Remark 1.12.* The proof by Fano is not rigorous, so the second question (rationality of hypersurface) is now considered as results of

- Clemens-Griffiths (deg = 3)
- Iskovskih-Manin (deg  $\geq 4$ )

## Classification of Fano 3-folds

Two invariants: Picard number  $\rho$  and index  $r$ .

**Definition 1.13.** Let  $X$  be a smooth projective variety.

$$\rho = \rho(X) := \dim_{\mathbb{Q}}((\text{Pic} X \otimes_{\mathbb{Z}} \mathbb{Q}) / \equiv) \in \mathbb{Z}_{\geq 0}.$$

It is equal to  $\dim_{\mathbb{Q}}((\text{Div} X \otimes_{\mathbb{Z}} \mathbb{Q}) / \equiv)$ , where  $\text{Div} X$  is the group of Weil divisors so that  $\text{Div} X \otimes_{\mathbb{Z}} \mathbb{Q}$  contains the formal linear combinations of prime divisors over  $\mathbb{Q}$ , and where the equivalence relation is given by  $D \equiv D'$  iff  $D \cdot C = D' \cdot C$  for every curve on  $X$ . From the intersection theory,  $D \cdot C = \mathcal{O}_X(D) \cdot C = \deg(\mu^* \mathcal{O}_X(D))$  for  $\mu : C^N \rightarrow C \hookrightarrow X$  (composition of normal and closed immersion). Then,  $D \in \text{Div} X \otimes_{\mathbb{Z}} \mathbb{Q}$  implies that there is  $m \in \mathbb{Z}_{\geq 0}$  such that  $mD \in \text{Div} X$ , then  $D \cdot C := \frac{1}{m}((mD) \cdot C)$ .

*Remark 1.14.* Let  $X$  be a Fano variety. Then,  $\text{Pic} X \cong \text{Pic} X / \equiv \cong \mathbb{Z}^{\oplus \rho(X)}$ . In particular,  $D \sim D'$  implies  $D \equiv D'$ .

**Definition 1.15.** Let  $X$  be a Fano variety.

$$r = r_X := \text{the largest positive integer that divides } K_X,$$

that is, there is a divisor  $H$  such that  $-K_X \sim rH$ , but for  $s > r$  there is no divisor  $H$  such that  $-K_X \sim sH$ .

We shall prove  $1 \leq r \leq \dim X + 1$  (for  $\dim X = 3$ , then  $r = 1, 2, 3, 4$ ).

**Example 1.16.** Let  $X = \mathbb{P}^3$ . Then,  $\text{Pic} X \cong \mathbb{Z}H$ , where  $H$  is a hyperplane, and  $-K_X \equiv 4H$ , hence  $\rho = 1$  and  $r = 4$ .

So here is the outline:

1.  $r \geq 2$ : Iskovskih, Fujita
2.  $\rho = r = 1$ : Iskovskih, Fujita
3.  $\rho \geq 2$ : Mori-Mukai

For 1,  $\Delta$ -genus(Fujita) is used, and for 2 and 3, the cone theorem(minimal model program) is used. When  $\dim X = 2$ , using MMP, a del Pezzo surface  $X$  is reduced to  $\mathbb{P}^2$  or  $\mathbb{P}^1 \times \mathbb{P}^1$ . When  $\dim X = 3$ , we have primitive Fano threefolds.

Our plan:

1. Cone theorem(mainly 2-dim)
  2.  $r \geq 2$
  3.  $\rho = r = 1$
  4.  $\rho \geq 2$  (primitive)
  5.  $\rho \geq 2$  (imprimitive)
- 

## Cone theorem

**Theorem 1.17** (Cone theorem, Mori, 1982). *Let  $X$  be a Fano variety. Then, there is rational curves  $l_1, \dots, l_m$  such that*

$$NE(X) = \sum_{i=1}^m \mathbb{R}_{\geq 0}[l_i] \quad \text{and} \quad -K_X \cdot l_i \leq \dim X + 1.$$

When  $\rho = 3$ ,  $NE(X) \subset N_1(X) \cong \mathbb{R}^{\rho(X)}$  is a triangular pyramid.

**Definition 1.18.** Let  $X$  be a smooth projective variety.

1.  $Z_1(X) := \bigoplus_{C: \text{curve on } X} \mathbb{Z}C$ ,
2.  $N_1(X) := (Z_1(X) \otimes_{\mathbb{Z}} \mathbb{R}) / \equiv$ , where  $Z \equiv Z'$  iff  $L \cdot Z = L \cdot Z'$  for all  $L \in \text{Pic} X$ .

It is well-known that

$$N_1(X) \times \left( \frac{\text{Pic} X \otimes_{\mathbb{Z}} \mathbb{R}}{\equiv} \right) \rightarrow \mathbb{R}$$

induces a bijection

$$N_1(X) \rightarrow \text{Hom}_{\mathbb{R}} \left( \frac{\text{Pic} X \otimes_{\mathbb{Z}} \mathbb{R}}{\equiv}, \mathbb{R} \right),$$

therefore  $\dim_{\mathbb{R}} N_1(X) = \rho(X)$ .

**Definition 1.19.** Let  $X$  be a smooth projective variety.

1. For  $Z \in Z_1(X) \otimes \mathbb{R}$ , denote by  $[Z] \in N_1(X)$  the numerical equivalence class of  $Z$ .
2. For  $Z \in Z_1(X) \otimes \mathbb{R}$  is an effective 1-cycle.
3.  $NE(X) := \{[Z] \in N_1(X) : Z \text{ effective 1-cycles}\}$

*Remark 1.20.*  $NE(X)$  is a convex cone.

**Example 1.21.** Let  $X := \mathbb{P}^1 \times \mathbb{P}^1$ . Let  $l_i = \pi_i^{-1}(*)$  for  $i = 1, 2$  be any fibers. Then,  $NE(X) = \mathbb{R}_{\geq 0}[l_1] + \mathbb{R}_{\geq 0}[l_2]$ . One direction is clear, and for the opposite, pick  $[D] = [a_1 C_1 + \dots + a_r C_r] \in NE(X)$  ( $a_i \geq 0$ ). It is enough to show  $C_i \equiv b_1 l_1 + b_2 l_2$  for some  $b_1, b_2 \geq 0$ . Fix a curve  $C$  on  $X$ . Note that since  $\text{Pic} X = \mathbb{Z}l_1 \oplus \mathbb{Z}l_2$ , we have  $C \equiv b_1 l_1 + b_2 l_2$ , so  $0 \leq C \cdot l_i = (b_1 l_1 + b_2 l_2) \cdot l_i = b_i l_1 \cdot l_2 > 0$ , we are done.

## 2 Day 2: April 13

### Extremal rays

**Definition 2.1.** Let  $X$  be a Fano variety. A ray  $R$  is called an extremal ray (of  $NE(X)$  or of  $X$ ) if  $\zeta, \xi \in NE(X)$  and  $\zeta + \xi \in R$  imply  $\zeta, \xi \in R$ .

**Theorem 2.2** (Contraction theorem). Let  $X$  be a Fano variety,  $R = \mathbb{R}_{\geq 0}[l]$  an extremal ray for a curve  $l$  on  $X$ . Then, there is a unique morphism  $f : X \rightarrow Y$  such that

- (i)  $Y$  is a projective normal variety,
- (ii)  $f_*\mathcal{O}_X = \mathcal{O}_Y$ ,
- (iii) For a curve  $c$  on  $X$ ,  $f(c)$  is point iff  $[c] \in R$ .

Moreover, we have  $\rho(X) = \rho(Y) + 1$  and an exact sequence  $0 \rightarrow \text{Pic } Y \xrightarrow{f^*} \text{Pic } X \xrightarrow{l} \mathbb{Z}$ . The morphism  $f$  is called the contraction morphism of  $R$ .

*Proof.* See [Kollár-Mori]. □

**Theorem 2.3.** Let  $X$  be a del Pezzo surface. Let  $R = \mathbb{R}_{\geq 0}[l]$  be an extremal ray for a curve  $l$  on  $X$  and  $f : X \rightarrow Y$  be its contraction. Then, one of the following holds:

- (A)  $l$  is a  $(-1)$ -curve and  $f$  is a blow down of  $l$  (hence  $\dim Y = 2$ ),
- (B)  $\dim Y = 1$  (i.e.  $Y$  is a smooth projective curve) and  $\rho(X) = 2$ , and  $f$  is a  $\mathbb{P}^1$ -bundle with fiber  $l$ .
- (C)  $\dim Y = 0$  (i.e.  $Y = \text{Spec } \mathbb{C}$ ) and  $\rho(X) = 1$ .

**Remark 2.4.** Let  $Y$  be a smooth projective surface and  $f : X \rightarrow Y$  be the blowup at a point  $P \in Y$ . Then,  $l := f^{-1}(P)$  satisfies  $l \cong \mathbb{P}^1$  and  $l^2 = -1$ ; called  $(-1)$ -curve. In this case we say  $f$  is the blowdown of  $l$ .

**Remark 2.5.** Let  $X$  be a del Pezzo surface and  $\rho(X) = 1$ . Then, it is known that  $X \cong \mathbb{P}^2$ .

**Exercise 2.6.** Show the above remark.

**Remark 2.7.** Let  $X$  be a smooth projective rational surface. If there is no  $(-1)$ -curve on  $X$ , then  $X \cong \mathbb{P}^2$  or  $X$  is isomorphic to the Hirzebruch surface  $\mathbb{P}_{\mathbb{P}^1}(\mathcal{O}_{\mathbb{P}^1} \oplus \mathcal{O}_{\mathbb{P}^1}(n))$ , where  $n \in \mathbb{Z}_{\geq 0} \setminus \{1\}$ .

**Remark 2.8.** Let  $X$  be a del Pezzo surface and  $f : X \rightarrow Y$  be a  $\mathbb{P}^1$ -bundle on a smooth projective curve  $Y$ . Then,  $Y = \mathbb{P}^1$  and  $X \cong \mathbb{P}_{\mathbb{P}^1}(\mathcal{O}_{\mathbb{P}^1} \oplus \mathcal{O}_{\mathbb{P}^1}(n))$ ,  $n \in \{0, 1\}$ .

*Sketch.* Leray spectral sequence gives  $H^1(Y, f_*\mathcal{O}_X (= \mathcal{O}_Y)) \hookrightarrow H^1(X, \mathcal{O}_X) = 0$ , so  $H^1(Y, \mathcal{O}_Y) = 0$  implies  $Y = \mathbb{P}^1$ .

Also,  $\mathbb{P}^1$ -bundle,  $X \cong \mathbb{P}_{\mathbb{P}^1}(E)$  of rank two, it is well known that  $E \cong \mathcal{O}_{\mathbb{P}^1}(a) \oplus \mathcal{O}_{\mathbb{P}^1}(b)$  and  $X \cong \mathbb{P}_{\mathbb{P}^1}(\mathcal{O}(a) \oplus \mathcal{O}(b)) \cong \mathbb{P}_{\mathbb{P}^1}(\mathcal{O} \oplus \mathcal{O}(b-a))$  for  $n := b-a \geq 0$ . It is known that for a  $\mathbb{P}^1$ -bundle over  $\mathbb{P}^1$  there is a section  $c$  such that  $c^2 = -n$ , then  $n \in \{0, 1\}$ . □

**Lemma 2.9.** Let  $X$  be a del Pezzo surface and  $C$  a curve on  $X$ . Then,  $C^2 \geq -1$ .

*Proof.* Write  $(K_X + C) \cdot C = 2h^1(C, \mathcal{O}_C) - 2$ . Recall that  $(\omega_X \otimes \mathcal{O}_X(C))|_C \cong \omega_C$  holds even if  $C$  is a singular curve. Hence,  $C^2 \geq -K_X \cdot C - 2 \geq 1 - 2 = -1$ . □

**Example 2.10.** Let  $X = \mathbb{P}^1 \times \mathbb{P}^1$  and  $l_i = \pi_i^{-1}(*)$  fibers. Then, each projection map  $\pi_i$  corresponds to the extremal rays  $\mathbb{R}_{\geq 0}[l_i]$ .

**Example 2.11.** Let  $X = \mathbb{P}^2$ . Then,  $NE(X) = \mathbb{R}_{\geq 0}[l] = \mathbb{R}_{\geq 0}[l'] = \dots$  since  $N_1(X) = \mathbb{R}^{\rho(X)} = \mathbb{R}$ .

**Example 2.12.** Let  $X = \mathbb{P}_{\mathbb{P}^1}(\mathcal{O}_{\mathbb{P}^1} \oplus \mathcal{O}_{\mathbb{P}^1}(1))$ , which is del Pezzo. Then, if  $f$  is a blowdown of a section  $l \cong \mathbb{P}^1$ , then  $\rho(Y) = 1$  and  $Y \cong \mathbb{P}^2$ . Then, we have two extremal rays  $[l]$  and  $[l']$  which correspond to  $f$  and  $\pi$  respectively.

**Remark 2.13.** Let  $X$  be a del Pezzo surface with  $\rho(X) \geq 3$ . Then,

$$\{\text{extremal rays}\} \leftrightarrow \{(-1)\text{-curves}\}.$$

Therefore, a del Pezzo surface has a finitely many  $(-1)$ -curves.

**Example 2.14.** Let  $f : X \rightarrow \mathbb{P}^2$  be a blowup at two points  $P$  and  $Q$  with  $l_P = f^{-1}(P)$  and  $l_Q = f^{-1}(Q)$ . Lifting a line  $m$  passing through  $P$  and  $Q$ , we obtain  $m_X$  the proper transform of  $m$ . Then,  $\rho(X) = 3$  and  $NE(X) = \mathbb{R}_{\geq 0}[l_P] + \mathbb{R}_{\geq 0}[l_Q] + \mathbb{R}_{\geq 0}[m_X]$ .

**Remark 2.15.** Let  $X \subset \mathbb{P}^3$  be a smooth cubic surface, for example,  $X : x^3 + y^3 + z^3 + w^3 = 0$ . It is well-known that  $X$  has exactly 27  $(-1)$ -curves so that  $NE(X) = \sum_{i=1}^{27} \mathbb{R}_{\geq 0}[l_i]$ .

**Remark 2.16.** Minimal model program for del Pezzo surfaces.

**Remark.** Let  $X \cong \mathbb{P}_{\mathbb{P}^1}(\mathcal{O}_{\mathbb{P}^1} \oplus \mathcal{O}_{\mathbb{P}^1}(n))$  with  $n \in \{0, 1\}$ .

If  $n = 0$ , then  $X \cong \mathbb{P}_{\mathbb{P}^1}(\mathcal{O}_{\mathbb{P}^1} \oplus \mathcal{O}_{\mathbb{P}^1}) \cong \mathbb{P}^1 \times \mathbb{P}^1$ .

If  $n = 1$ , then  $X \cong \mathbb{P}_{\mathbb{P}^1}(\mathcal{O}_{\mathbb{P}^1} \oplus \mathcal{O}_{\mathbb{P}^1}(1))$ , there is a  $(-1)$ -curve on  $X$  (cf.(2.11))

**Outline of (2.3).** For an extremal ray  $R = \mathbb{R}_{\geq 0}[l]$ , (A) for  $l^2 < 0$ , (B) for  $l^2 = 0$ , (C) for  $l^2 > 0$ . □

**Proposition 2.17.** Let  $X$  be a del Pezzo surface and  $l$  be a curve on  $X$  with  $l^2 < 0$ . Then,

- (a)  $l$  is a  $(-1)$ -curve,
- (b)  $\mathbb{R}_{\geq 0}[l]$  is an extremal ray,
- (c) the contraction of  $R$  is the blowdown of  $l$ .

**Proof.** (a) TFAE:

- (i)  $l$  is a  $(-1)$ -curve,
- (ii)  $l \cong \mathbb{P}^1$  and  $l^2 = -1$ ,
- (iii)  $K_X \cdot l = l^2 = -1$ ,
- (iv)  $K_X \cdot l < 0$  and  $l^2 < 0$ .

Here  $X$  is a smooth projective surface and  $l$  a curve on it. Note (i) and (ii) are equivalent by definition. The equivalence between (ii) and (iii) is due to  $(K_X + l) \cdot l = 2h^1(l, \mathcal{O}_l) - 2 \geq -2$ . The equivalence between (iii) and (iv) is clear.

(b) Omitted.

(c) Let  $f : X \rightarrow Y$  blowdown of  $l$  and  $P := f(l)$ . Recall that  $f$  is a contraction of  $R$  iff

- (i)  $Y$  is a projective normal variety,

(ii)  $f_*\mathcal{O}_X = \mathcal{O}_Y$ ,

(iii) for a curve  $C$  on  $X$ ,  $f(C)$  is a point iff  $[C] \in \mathbb{R}_{\geq 0}[l]$ .

It follows (ii) from the following lemma (2.18). For (iii),  $(\Rightarrow)$  is clear.  $(\Leftarrow)$  Suppose  $[C] \in \mathbb{R}_{\geq 0}[l]$  and  $C \neq l$  so that  $C \cdot l \geq 0$ . Then,  $C \equiv al$  for  $a \in \mathbb{R}_{\geq 0}$ , and  $a > 0$  since  $C \cdot H = al \cdot H$  for ample  $H$ . Now  $0 \leq C \cdot l = al \cdot l = a(> 0) \cdot l^2 (= -1) < 0$ , a contradiction.  $\square$

**Lemma 2.18.** *If  $f$  is a projective birational morphism of normal varieties, then  $f_*\mathcal{O}_X = \mathcal{O}_Y$ .*

*Proof.* Consider the Stein factorization

$$\begin{array}{ccc} X & \xrightarrow{f} & Y \\ & \searrow g \quad \nearrow h & \\ & Z & \end{array}$$

such that  $g_*\mathcal{O}_X = \mathcal{O}_Z$  and  $h$  finite. Then,

$$\begin{array}{ccc} K(X) & \xleftarrow{\cong} & K(Y) \\ & \nwarrow \quad \swarrow & \\ & K(Z) & \end{array}$$

implies  $Z \xrightarrow{h} Y$  is finite birational morphism, and  $A \hookrightarrow B$  is integral extension with  $K(A) = K(B)$  where  $\text{Spec} A \subset Y$  is affine open and  $\text{Spec} B$  is given by the pullback (inverse image of  $h$ ), hence  $A = B$ .  $\square$

**Lemma 2.19.** *Let  $X$  be a del Pezzo surface and  $\mathbb{R}_{\geq 0}[l]$  be an extremal ray for a curve  $l$  on  $X$ , whose contraction is  $f : X \rightarrow Y$ . Then,*

(A)  $l^2 < 0$  iff  $\dim Y = 2$ ,

(B)  $l^2 = 0$  iff  $\dim Y = 1$ ,

(C)  $l^2 > 0$  iff  $\dim Y = 0$ .

*Proof.* Next lecture.

For the case (C), we have done in (2.19)  $\square$

**Proposition 2.20** ((B)). *If  $l^2 = 0$ , then the fiber is isomorphic to  $\mathbb{P}^1$ .*

*Proof.* For  $P \in Y$ , let  $F := f^*P = \sum_{i=1}^r a_i C_i$  with  $a_i \in \mathbb{Z}_{>0}$  and  $C_i$  prime divisors.

**Claim 2.21.** *Every fiber is irreducible.*

*Proof.* If it is reducible, then there are  $C_1 \neq C_2$  in the fiber, then

$$F \cdot C_1 = \left( \sum_{i=1}^r a_i C_i \right) \cdot C_1 = a_1 C_1^2 + (\text{positive}),$$

so  $C_1^2 < 0$ . Then,  $C_i \equiv b_i l$ , so  $C_1^2 < 0$  implies  $l^2 < 0$  and  $C_1 \cdot C_2 \geq 0$  implies  $l^2 \geq 0$ , a contradiction.  $\square$

We can show that every fiber  $F$  is reduced:

$$(K_X + F) \cdot F = K_X \cdot F + F^2 = K_X \cdot F + 0 < 0,$$

by the adjunction,  $F \cong \mathbb{P}^1$ .  $\square$
