

A SOLUTION TO HAAGERUP'S PROBLEM AND POSITIVE HAHN-BANACH SEPARATION THEOREMS IN OPERATOR ALGEBRAS

IKHAN CHOI

ABSTRACT. We affirmatively resolve a question posed by Uffe Haagerup in 1975 on the positive version of the bipolar theorem on the dual spaces of C^* -algebras. As a direct consequence, we obtain a complete set of four positive Hahn-Banach separation theorems on von Neumann algebras, their preduals, C^* -algebras, and their duals.

1. INTRODUCTION

In this paper, we prove the following theorem.

Theorem. *Let M be a von Neumann algebra, and let A be a C^* -algebra.*

- (1) *If F is a σ -weakly closed convex hereditary subset of M^+ , then for any $x \in M^+ \setminus F$ there exists $\omega \in M_*^+$ such that $\omega(x) > 1$ and $\omega(x') \leq 1$ for all $x' \in F$.*
- (2) *If F_* is a norm closed convex hereditary subset of M_*^+ , then for any $\omega \in M_*^+ \setminus F_*$ there exists $x \in M^+$ such that $\omega(x) > 1$ and $\omega'(x) \leq 1$ for all $\omega' \in F_*$.*
- (3) *If F is a norm closed convex hereditary subset of A^+ , then for any $a \in A^+ \setminus F$ there exists $\omega \in A^{*+}$ such that $\omega(a) > 1$ and $\omega(a') \leq 1$ for all $a' \in F$.*
- (4) *If F^* is a weakly* closed convex hereditary subset of A^{*+} , then for any $\omega \in A^{*+} \setminus F^*$ there exists $a \in A^+$ such that $\omega(a) > 1$ and $\omega'(a) \leq 1$ for all $\omega' \in F^*$.*

Recall the definition of hereditary subsets.

Definition 1.1. Let E be a partially ordered real vector space. A subset F of the positive cone E^+ is called *hereditary* if $0 \leq x \leq y$ in E with $y \in F$ implies $x \in F$, or equivalently $F = (F - E^+)^+$.

The first three parts of the above theorem were originally proved by Uffe Haagerup in his master's thesis [Haa75], where he also posed a problem that asks if (4) holds at the end. The first part (1) plays a major role in the proof that σ -weakly lower semi-continuous weight of a von Neumann algebra is given by the pointwise supremum of a set of positive normal linear functionals. The statements in the original paper are written in terms of positive forms of the bipolar theorem $F^{r+r+} = F$ instead of the Hahn-Banach separation theorem as presented above, where the positive polar F^{r+} can be defined as

$$F^{r+} := F^r \cap E^{*+} = \{x^* \in E^{*+} : \sup_{x \in F} x^*(x) \leq 1\}$$

Key words and phrases. C^* -algebras, von Neumann algebras, normal weights.

as the positive part of the real polar in an ordered real locally convex space E . They are easily checked to be equivalent using the usual Hahn-Banach separation theorem.

Although the first three are already known results by Haagerup on the contrary to (4), we provide different proofs of them in order to motivate the idea of the proof of (4). In more detail, when Haagerup proved (1), he heavily used the σ -strong topology and the strong continuity of continuous bounded functions, but such a nice dual topology for the dual pair of a von Neumann algebra and its σ -weak dual has no analogue in the dual of a C^* -algebra. In this context, we provide a proof of (1) using only the σ -weak topology and extend the idea to prove (4) within the weak* topology. On the other hand, Haagerup also used (1) to prove (2), but we show that the Krein Šmulian theorem, which is essential in the proof of (1) and (4), is not required in (2) and we can prove it directly. The part (3) is a straightforward corollary of (1).

In Section 2, we introduce some preliminaries for the main proofs, most of which are well-known. The notations introduced in Section 2 will be repeatedly used in Section 3, where we give the proofs of the four positive Hahn-Banach separation theorems.

2. PRELIMINARIES

2.1. Suppression by the one-parameter family of functional calculi. The first step of the proof is the reformulation of the theorem into an inclusion problem. More precisely, we need to prove statements of the form $(\overline{F - E^+})^+ \subset F$. In other words, when x_i is a net in $F - E^+$ convergent to $x \geq 0$ in a partially ordered real locally convex space E , there is a majorizing net $y_i \in F$ satisfying $x_i \leq y_i$, we then need to find $y \in F$ such that $x \leq y$ in order to deduce $x \in F$ with the hereditariness of F . The problem is that y_i has of course no limit points in general. To address this, we consider the following one-parameter family of real functions.

Definition 2.1. For $\delta > 0$, we define a function $f_\delta : (-\delta^{-1}, \infty) \rightarrow \mathbb{R}$ such that

$$f_\delta(t) := t(1 + \delta t)^{-1}, \quad t > -\delta^{-1}.$$

It has many interesting properties such as operator monotonicity and concavity, strong convergence to the identity as $\delta \rightarrow 0$, and the semi-group property in the sense that $f_\delta(f_{\delta'}(t)) = f_{\delta+\delta'}(t)$ on a suitable domain of $t \in \mathbb{R}$. We will only use the operator monotonicity and the boundedness from above, given each fixed $\delta > 0$. With these functions, for example in the situation of (1), we can suppress the net y_i to define a bounded net $f_\delta(y_i)$ and take a σ -weakly convergent subnet to get $f_\delta(x) \in F$ by the hereditariness of F . Then, the limit $\delta \rightarrow 0$ and the closedness of F will give $x \in F$.

Unlike the σ -strong topology, we cannot expect the operation of taking functional calculus to be continuous with respect to the σ -weak topology. For instance, when a self-adjoint net $x_i \in B(H)^{sa}$ satisfies $-(2\delta)^{-1} \leq x_i$ for all i and $x_i \rightarrow x$ σ -weakly, it does not necessarily follow $f_\delta(x_i) \rightarrow f_\delta(x)$ σ -weakly. The following lemma will be frequently used, and it allows us to approximate $f_\delta(x)$ directly with the σ -weakly convergent net x_i instead of $f_\delta(x_i)$, while accompanied by small errors.

Lemma 2.2. Let $\delta > 0$ and $t \in \mathbb{R}$.

- (1) If $|t| \leq 2^{-1}\delta^{-\frac{1}{4}}$ and $\delta \leq 1$, then $t \leq f_\delta(t) + \delta^{\frac{1}{2}}$.
- (2) If $t \geq 0$ and $c \geq 0$, then $f_\delta(t+c) \leq f_\delta(t) + c$.
- (3) If $0 \leq t \leq 1$, then $(1+\delta)^{-1}t \leq f_\delta(t)$.

Proof. (1) Since $\delta \leq 1 < 2^{\frac{4}{3}}$ implies $t \geq -2^{-1}\delta^{-\frac{1}{4}} > -\delta^{-1}$, the value $f_\delta(t)$ is well-defined. The inequality is equivalent to $\delta^{\frac{1}{2}}t^2 - \delta t \leq 1$, and it holds for $|t| \leq 2^{-1}\delta^{-\frac{1}{4}}$.

(2) The inequality holds for $t = 0$, so we can check by differentiation with respect to t for fixed c .

(3) It follows from $t(1+\delta t) \leq t(1+\delta)$. \square

2.2. Bounded commutant Radon-Nikodym derivatives. In the proofs of (2) and (4), we need to suppress linear functionals instead of operators, so we introduce the notion of Radon-Nikodym derivatives to convert functionals to operators as follows.

Definition 2.3. Let M be a von Neumann algebra, and let $\psi \in M_*^+$. Consider the Gelfand-Naimark-Segal representation $\pi : M \rightarrow B(H)$ associated to ψ , together with the canonical cyclic vector $\Omega \in H$. Then, we have a positive bounded linear map $\theta : \pi(M)' \rightarrow M_*$ defined such that

$$\theta(h)(x) := \langle h\pi(x)\Omega, \Omega \rangle, \quad h \in \pi(M)', \quad x \in M.$$

Although it is not a standard terminology, we will call this linear map θ the (bounded) *commutant Radon-Nikodym map* associated to ψ in this paper.

Let θ be the commutant Radon-Nikodym map associated to $\psi \in M_*^+$. When M is commutative so that $\pi(M) = \pi(M)'$, the inverse map θ^{-1} assigns to a linear functional an operator, which is exactly the Radon-Nikodym derivative in the classical measure-theoretic sense. We include the adjective “commutant” to avoid confusion with Connes’ Radon-Nikodym derivatives. The image of θ associated to ψ is described by

$$\text{im } \theta = \{\omega \in M_* : \text{there is } C > 0 \text{ such that } |\omega(x)| \leq C\psi(x) \text{ for all } x \in M^+\},$$

and the Radon-Nikodym derivative $\theta^{-1}(\omega) \in M_*$ of $\omega \in \text{im } \theta$ satisfies the bound $\|\theta^{-1}(\omega)\| \leq C$, where C is a constant in the above description of the image of θ . In the proof of (2), for a sequence $\omega_n \in F_* - M_*^+$, a single reference functional $\psi \in M_*^+$ is constructed such that $|\omega_n(x)| \leq C\psi(x)$ for all $x \in M^+$ and n , however in (4), we take $\psi_i \in A^{*+}$ such that it depends on the net $\omega_i \in F^* - A^{*+}$ to have $|\omega_i(a)| \leq C\psi_i(a)$ for all $a \in A^+$ and i . The dependence of ψ_i on i is a key idea of the proof of (4).

Let $\omega \in M_*^{sa}$. The Jordan decomposition theorem gives a unique pair $\omega_+, \omega_- \in M_*^+$ of positive normal linear functionals such that $\omega = \omega_+ - \omega_-$ and $\|\omega\| = \|\omega_+\| + \|\omega_-\|$. The absolute value of ω is defined as $[\omega] := \omega_+ + \omega_-$. Note that we always have $|\omega(x)| \leq [\omega](x)$ for all $x \in M^+$, but unless M is commutative, then for $\omega \in M_*^{sa}$ and $\psi \in M_*^+$ we cannot expect $[\omega] \leq \psi$ when $|\omega(x)| \leq \psi(x)$ for all $x \in M^+$. Note also that when A is a C^* -algebra and ω_i is a net in A^{*sa} , we have $\omega_{i+} \rightarrow 0$ in norm if $\omega_i \rightarrow 0$ in norm, but we do not have $\omega_{i+} \rightarrow 0$ weakly* in general if $\omega_i \rightarrow 0$ weakly* in A^* . For further details, see IV.3 for the commutant Radon-Nikodym map and III.4 for the Jordan decomposition theorem in [Tak02].

3. PROOFS OF THEOREMS

Theorem 3.1. *Let M be a von Neumann algebra, and consider the dual pair (M^{sa}, M_*^{sa}) . If F is a σ -weakly closed convex hereditary subset of M^+ , then $F = F^{r+r+}$. Equivalently, if $x \in M^+ \setminus F$, then there is $\omega \in M_*^+$ such that $\omega(x) > 1$ and $\omega(x') \leq 1$ for $x' \in F$.*

Proof. Since the positive polar is represented by the real polar

$$F^{r+} = F^r \cap M_*^+ = F^r \cap (-M^+)^r = (F \cup -M^+)^r = (F - M^+)^r,$$

the positive bipolar can be written as $F^{r+r+} = (F - M^+)^{r+r+} = (\overline{F - M^+})^+$ by the usual real bipolar theorem, where the closure is for the σ -weak topology. Because $F = (F - M^+)^+ \subset (\overline{F - M^+})^+$, it suffices to prove the opposite inclusion $(\overline{F - M^+})^+ \subset F$.

Define

$$G := \left\{ x \in M^{sa} : \begin{array}{l} \text{for any sufficiently small } \delta > 0 \\ \text{there is } y_\delta \in F \text{ such that} \\ \|y_\delta\| \leq \delta^{-1} \text{ and } x \leq y_\delta + \delta^{\frac{1}{2}} \end{array} \right\}.$$

We prove $(\overline{F - M^+})^+ \subset F$ via three steps, $F - M^+ \subset G$, $G^+ \subset F$, and $\overline{G} \subset G$.

Let $x \in F - M^+$, with $y \in F$ such that $x \leq y$. If we define $y_\delta := f_\delta(y)$, then for sufficiently small $\delta > 0$ such that $\|x\| \leq 2^{-1}\delta^{-\frac{1}{4}}$ and $\delta \leq 1$, we have $x \leq f_\delta(x) + \delta^{\frac{1}{2}} \leq y_\delta + \delta^{\frac{1}{2}}$, so $x \in G$.

Let $x \in G^+$. Take $y_\delta \in F$ such that $\|y_\delta\| \leq \delta^{-1}$ and $x \leq y_\delta + \delta^{\frac{1}{2}}$ for sufficiently small δ . For any $\delta' > 0$, we have

$$0 \leq (1 + \delta'\|x\|)^{-1}x \leq f_{\delta'}(x) \leq f_{\delta'}(y_\delta + \delta^{\frac{1}{2}}) \leq f_{\delta'}(y_\delta) + \delta^{\frac{1}{2}}.$$

Since $f_{\delta'}(y_\delta) \in F$ is bounded for fixed δ' , by considering the limit along a cofinal ultrafilter on the set of δ , we have $(1 + \delta'\|x\|)^{-1}x \in F$, so the limit $\delta' \rightarrow 0$ gives $x \in F$.

Now it suffices to show G is σ -weakly closed. We claim that for any $r > 0$ we have

$$\overline{(F - M^+) \cap M_{2r}} \subset G, \quad G \cap M_r \subset \overline{(F - M^+) \cap M_{2r}},$$

where $M_r := \{x \in M : \|x\| \leq r\}$. If these are true, then

$$G \cap M_r = \overline{(F - M^+) \cap M_{2r}} \cap M_r$$

is σ -weakly closed and convex in M for all $r > 0$, so the Krein-Šmulian theorem proves that G is σ -weakly closed.

Let $x_i \in (F - M^+) \cap M_{2r}$ be a net such that $x_i \rightarrow x$ σ -weakly in M and $\|x_i\| \leq 2r$ for all i . Take $y_i \in F$ such that $x_i \leq y_i$ for all i . For sufficiently small $\delta > 0$ such that $2r \leq 2^{-1}\delta^{-\frac{1}{4}}$ and $\delta \leq 1$, we have $x_i \leq f_\delta(x_i) + \delta^{\frac{1}{2}} \leq f_\delta(y_i) + \delta^{\frac{1}{2}}$. By considering a cofinal ultrafilter on the index set of i , if we define y_δ as the σ -weak ultralimit of $f_\delta(y_i)$ of this ultrafilter, then we have $\|y_\delta\| \leq \delta^{-1}$ and $x \leq y_\delta + \delta^{\frac{1}{2}}$, so $x \in G$.

Let $x \in G \cap M_r$. Take $y_\delta \in F$ such that $\|y_\delta\| \leq \delta^{-1}$ and $x \leq y_\delta + \delta^{\frac{1}{2}}$ for sufficiently small δ . If $\delta^{\frac{1}{2}} < r$, then $x - \delta^{\frac{1}{2}} \in (F - M^+) \cap M_{2r}$ σ -weakly converges to x as $\delta \rightarrow 0$, so $x \in \overline{(F - M^+) \cap M_{2r}}$. This completes the proof. \square

Theorem 3.2. *Let M be a von Neumann algebra, and consider the dual pair (M_*^{sa}, M_*^{sa}) . If F_* is a norm closed convex hereditary subset of M_*^+ , then $F_* = F_*^{r+r+}$. Equivalently, if $\omega \in M_*^+ \setminus F_*$, then there is $x \in M^+$ such that $\omega(x) > 1$ and $\omega'(x) \leq 1$ for $\omega' \in F_*$.*

Proof. It is enough to prove $(\overline{F_* - M_*^+})^+ \subset F_*$, where the closure is for the weak topology or equivalently for the norm by the convexity of $F_* - M_*^+$, so we begin our proof by fixing $\omega \in (\overline{F_* - M_*^+})^+$ and a sequence $\omega_n \in F_* - M_*^+$ such that $\omega_n \rightarrow \omega$ in norm of M_* . Take $\varphi_n \in F_*$ such that $\omega_n \leq \varphi_n$ for all n . We may assume $\|\omega_n - \omega\| \leq 2^{-n}$ for all n by passing to a subsequence. Define

$$\psi := \omega + \sum_n [\omega_n - \omega] + \sum_n 2^{-n} \frac{\varphi_n}{1 + \|\varphi_n\|}$$

in M_*^+ , and let θ be the commutant Radon-Nikodym map associated to ψ . Since $-\psi \leq \omega_n \leq \psi$ implies the boundedness $\|\theta^{-1}(\omega_n)\| \leq 1$ for all n , the weak convergence $\omega_n \rightarrow \omega$ in M_* implies the convergence $\theta^{-1}(\omega_n) \rightarrow \theta^{-1}(\omega)$ in the weak operator topology of $\pi(M)'$. By the Mazur lemma, we can take a net ω_i in the convex hull of ω_n such that $\theta^{-1}(\omega_i) \rightarrow \theta^{-1}(\omega)$ strongly in $\pi(M)'$, and the corresponding $\varphi_i \in F_*$ can be defined such that $\omega_i \leq \varphi_i$ for all i . In fact, the net ω_i can be taken to be a sequence because the commutant is σ -finite by the existence of the separating vector, but it is not necessary in here. For each i and $0 < \delta < 1$, define

$$\omega_\delta := \theta(f_\delta(\theta^{-1}(\omega))), \quad \omega_{i,\delta} := \theta(f_\delta(\theta^{-1}(\omega_i))), \quad \varphi_{i,\delta} := \theta(f_\delta(\theta^{-1}(\varphi_i))),$$

where the functional calculus $f_\delta(h_i)$ is well-defined because $-1 \leq h_i$ for all i . Since $f_\delta(\theta^{-1}(\omega_i)) \rightarrow f_\delta(\theta^{-1}(\omega))$ strongly in the commutant by the strong continuity of f_δ , we have $\omega_{i,\delta} \rightarrow \omega_\delta$ weakly in M_* for each δ . Taking a cofinal ultrafilter on the index set of i , define k_δ as the σ -weak ultralimit of $f_\delta(\theta^{-1}(\varphi_i))$ in the commutant, and let $\varphi_\delta := \theta(k_\delta)$ so that $\varphi_{i,\delta} \rightarrow \varphi_\delta$ weakly in M_* for each δ . Since $\varphi_i \in F_*$, $0 \leq \varphi_{i,\delta} \leq \varphi_i$ implies $\varphi_{i,\delta} \in F_*$, and the weak convergence $\varphi_{i,\delta} \rightarrow \varphi_\delta$ in M_* implies $\varphi_\delta \in F_*$. Furthermore, $\omega_i \leq \varphi_i$ implies $\omega_{i,\delta} \leq \varphi_{i,\delta}$ and $0 \leq \omega_\delta \leq \varphi_\delta$, so $\omega_\delta \in F_*$. The weak convergence $\omega_\delta \rightarrow \omega$ in M_* as $\delta \rightarrow 0$ finally implies $\omega \in F_*$, so we get $(\overline{F_* - M_*^+})^+ \subset F_*$. \square

Theorem 3.3. *Let A be a C^* -algebra, and consider the dual pair (A^{sa}, A^{*sa}) . If F is a norm closed convex hereditary subset of A^+ , then $F = F^{r+r+}$. Equivalently, if $a \in A^+ \setminus F$, then there is $\omega \in A^{*+}$ such that $\omega(a) > 1$ and $\omega(a') \leq 1$ for $a' \in F$.*

Proof. We directly prove the separation without invoking the arguments of positive bipolars. Denote by F^{**} the σ -weak closure of F in the universal von Neumann algebra A^{**} . We first show that F^{**} is hereditary subset of A^{*+} . Suppose $0 \leq x \leq y$ in A^{**} and $y \in F^{**}$. Then, there is $z \in A^{**}$ such that $x^{\frac{1}{2}} = zy^{\frac{1}{2}}$. Take bounded nets b_i in F and c_i in A such that $b_i \rightarrow y$ and $c_i \rightarrow z$ σ -strongly* in A^{**} using the Kaplansky density theorem. We may assume the indices of these two nets are shared by considering the product directed set. Since both the multiplication and the involution of a von Neumann algebra on bounded parts are continuous in the σ -strong* topology, and since the square root on a positive bounded interval is strongly continuous, we have the σ -strong* limit

$$x = y^{\frac{1}{2}} z^* z y^{\frac{1}{2}} = \lim_i b_i^{\frac{1}{2}} c_i^* c_i b_i^{\frac{1}{2}},$$

so we obtain $x \in F^{**}$ from $b_i^{\frac{1}{2}} c_i^* c_i b_i^{\frac{1}{2}} \in F$. Thus, F^{**} is hereditary in A^{**+} .

Let $a \in A^+ \setminus F$. If $a \in F^{**}$, then we have a net a_i in F such that $a_i \rightarrow a$ σ -weakly in A^{**} , which means that $a_i \rightarrow a$ weakly in A , and by the weak closedness of F in A we get a contradiction $a \in F^{**} \cap A = F$. It implies $a \in A^{**+} \setminus F^{**}$, so by Theorem 3.1, there is $\omega \in A^{**+}$ such that $\omega(a) > 1$ and $\omega(a') \leq 1$ for all $a' \in F \subset F^{**}$, and we are done. \square

Theorem 3.4. *Let A be a C^* -algebra, and consider the dual pair (A^{*sa}, A^{sa}) . If F^* is a weakly* closed convex hereditary subset of A^{*+} , then $F^* = (F^*)^{r+r+}$. Equivalently, if $\omega \in A^{*+} \setminus F^*$, then there is $a \in A^+$ such that $\omega(a) > 1$ and $\omega'(a) \leq 1$ for $\omega' \in F^*$.*

Proof. As above, we will prove $(\overline{F^* - A^{*+}})^+ \subset F^*$. Define

$$G^* := \left\{ \omega \in A^{*sa} : \begin{array}{l} \text{there is } \psi \in A^{*+}, \text{ and there is } \varphi_\delta \in F^* \\ \text{for any sufficiently small } \delta > 0, \text{ such that} \\ \|\psi\| \leq 1, \|\varphi_\delta\| \leq \delta^{-1}, \text{ and } \omega \leq \varphi_\delta + \delta^{\frac{1}{2}}\psi \end{array} \right\}.$$

It suffices to show $F^* - A^{*+} \subset G^*$, $G^{*+} \subset F^*$, and $\overline{G^*} \subset G^*$.

Let $\omega \in F^* - A^{*+}$. Take $\varphi \in F^*$ such that $\omega \leq \varphi$. Define, for $\delta > 0$,

$$\psi := \frac{[\omega]}{1 + \|\omega\|} + \frac{\varphi}{(1 + \|\omega\|)(1 + \|\varphi\|)}, \quad \varphi_\delta := \theta(f_\delta(\theta^{-1}(\varphi))),$$

where θ is the commutant Radon-Nikodym map associated to ψ . The norm conditions $\|\psi\| \leq 1$ and $\|\varphi_\delta\| \leq \delta^{-1}$ are easily checked. For sufficiently small $\delta > 0$ such that $\|\theta^{-1}(\omega)\| \leq 1 + \|\omega\| \leq 2^{-1}\delta^{-\frac{1}{4}}$ and $\delta \leq 1$, we have

$$\omega = \theta(\theta^{-1}(\omega)) \leq \theta(f_\delta(\theta^{-1}(\omega)) + \delta^{\frac{1}{2}}\psi) \leq \theta(f_\delta(\theta^{-1}(\varphi))) + \theta(\delta^{\frac{1}{2}}\psi) = \varphi_\delta + \delta^{\frac{1}{2}}\psi,$$

so $\omega \in G^*$.

Let $\omega \in G^{*+}$. Take $\psi \in A^{*+}$ and $\varphi_\delta \in F^*$ such that $\|\psi\| \leq 1$, $\|\varphi_\delta\| \leq \delta^{-1}$, and $\omega \leq \varphi_\delta + \delta^{\frac{1}{2}}\psi$, for any sufficiently small $\delta > 0$. Let $\psi_\delta := \omega + \delta\varphi + \psi$, and let θ_δ be the associated commutant Radon-Nikodym map. For any fixed $\delta' > 0$, since $0 \leq \theta_\delta^{-1}(\omega) \leq 1$, we have

$$\begin{aligned} 0 &\leq (1 + \delta')^{-1}\theta_\delta(\omega) \leq f_{\delta'}(\theta_\delta^{-1}(\omega)) \leq f_{\delta'}(\theta_\delta^{-1}(\varphi_\delta + \delta^{\frac{1}{2}}\psi)) \\ &\leq f_{\delta'}(\theta_\delta^{-1}(\varphi_\delta) + \delta^{\frac{1}{2}}\psi) \leq f_{\delta'}(\theta_\delta^{-1}(\varphi_\delta)) + \delta^{\frac{1}{2}}, \end{aligned}$$

and it implies $0 \leq (1 + \delta')^{-1}\omega \leq \theta_\delta(f_{\delta'}(\theta_\delta^{-1}(\varphi_\delta))) + \delta^{\frac{1}{2}}\psi_\delta$. Since $\|\psi_\delta\| \leq \|\omega\| + 2$ is bounded and $\theta_\delta(f_{\delta'}(\theta_\delta^{-1}(\varphi_\delta))) \in F^*$ is also bounded for fixed δ' , by considering the limit along a cofinal ultrafilter on the set of δ , we have $(1 + \delta')^{-1}\omega \in F^*$, so $\delta' \rightarrow 0$ gives $\omega \in F^*$.

To show G^* is weakly* closed, we claim for any $r > 0$ that

$$\overline{(F^* - A^{*+}) \cap A_{2r}^*} \subset G^*, \quad G^* \cap A_r^* \subset \overline{(F^* - A^{*+}) \cap A_{2r}^*},$$

where $A_r^* := \{\omega \in A^* : \|\omega\| \leq r\}$. If these are true, then

$$G^* \cap A_r^* = \overline{(F^* - A^{*+}) \cap A_{2r}^*} \cap A_r^*$$

is weakly* closed and convex in A^* for all $r > 0$, so the Krein-Šmulian theorem shows that G^* is weakly* closed.

Let $\omega_i \in (F^* - A^{*+}) \cap A_{2r}^*$ be a net such that $\omega_i \rightarrow \omega$ weakly* in A^* with $\|\omega_i\| \leq 2r$ for all i . Take $\varphi_i \in F^*$ such that $\omega_i \leq \varphi_i$ for all i , and define

$$\psi_i := \frac{[\omega_i]}{1 + \|\omega_i\|} + \frac{\varphi_i}{(1 + \|\omega_i\|)(1 + \|\varphi_i\|)}, \quad \varphi_{i,\delta} := \theta_i(f_\delta(\theta_i^{-1}(\varphi_i))),$$

where θ_i denotes the commutant Radon-Nikodym map associated to ψ_i . It clearly follows that $\|\psi_i\| \leq 1$ and $\|\varphi_{i,\delta}\| \leq \delta^{-1}$ for all i , and for sufficiently small $\delta > 0$ such that $1 + 2r \leq 2^{-1}\delta^{-\frac{1}{4}}$ and $\delta \leq 1$, we can also check

$$\omega_i = \theta_i(\theta_i^{-1}(\omega_i)) \leq \theta_i(f_\delta(\theta_i^{-1}(\omega_i)) + \delta^{\frac{1}{2}}) \leq \theta_i(f_\delta(\theta_i^{-1}(\varphi_i))) + \theta_i(\delta^{\frac{1}{2}}) = \varphi_{i,\delta} + \delta^{\frac{1}{2}}\psi_i.$$

Taking the limit along a cofinal ultrafilter on the index set of i , we obtain ψ and φ_δ for each δ by the limit of bounded nets ψ_i and $\varphi_{i,\delta}$ respectively, which satisfy $\omega \leq \varphi_\delta + \delta^{\frac{1}{2}}\psi$ with norm conditions $\|\psi\| \leq 1$ and $\|\varphi_\delta\| \leq \delta^{-1}$, so $\omega \in G^*$.

Let $\omega \in G^* \cap A_r^*$. Take $\psi \in A^{*+}$ and $\varphi_\delta \in F^*$ such that $\|\psi\| \leq 1$, $\|\varphi_\delta\| \leq \delta^{-1}$, and $\omega \leq \varphi_\delta + \delta^{\frac{1}{2}}\psi$, for any sufficiently small $\delta > 0$. If $\delta^{\frac{1}{2}} < r$, then $\omega - \delta^{\frac{1}{2}}\psi \in (F^* - A^{*+}) \cap A_{2r}^*$, converges to ω weakly* in A^* as $\delta \rightarrow 0$, we have $\omega \in \overline{(F^* - A^{*+}) \cap A_{2r}^*}$. This completes the proof. \square

Haagerup left in his paper [Haa75] a comment without a proof that Theorem 3.4 is not difficult when a C^* -algebra is commutative. As a final remark, we give a direct proof of this.

Corollary 3.5. *Let A be a commutative C^* -algebra, and consider the dual pair (A^{*sa}, A^{sa}) . If F^* is a weakly* closed convex hereditary subset of A^{*+} , then $F^* = (F^*)^{r+r+}$.*

Proof. We first see that $\omega_+ \leq \omega'_+$ if $\omega \leq \omega'$ in A^{*sa} . Consider the ramp functions $t \mapsto t_+ := \max\{0, t\}$ and $t \mapsto t_- := \max\{0, -t\}$ defined on $t \in \mathbb{R}$. Let $\omega \in A^{*sa}$ and $\psi \in A^{*+}$ such that ω belongs to the image of the commutant Radon-Nikodym map θ associated to ψ . Let $\pi : A \rightarrow B(H)$ be the Gelfand-Naimark-Segal representation associated to ψ with the canonical cyclic vector $\Omega \in H$. Let $p \in \pi(A)'$ be a projection such that $|\theta^{-1}(\omega)| = \theta^{-1}(\omega)p$. Then, $p \in \pi(A)''$ because $\pi(A)''$ is a maximal commutative subalgebra of $B(H)$ by Theorem III.1.2 in [Tak02], or in a straightforward way because we can identify $p \in \pi(A)'$ with a bounded linear functional $\pi(A)'' \rightarrow \mathbb{C} : (x \mapsto \langle x\pi(a)\Omega, \pi(b)\Omega \rangle) \mapsto \langle p\pi(a)\Omega, \pi(b)\Omega \rangle$, where $x \in \pi(A)''$ and $a, b \in A$. If we take $a \in A$ such that $\|\pi(a)\| \leq 1$ and $|\langle \theta^{-1}(\omega)(p - \pi(a))\Omega, \Omega \rangle| < \varepsilon$ for arbitrarily chosen $\varepsilon > 0$ using the Kaplansky density theorem, then the limit $\varepsilon \rightarrow 0$ on

$$\begin{aligned} \|\theta(\theta^{-1}(\omega)_+)\| + \|\theta(\theta^{-1}(\omega)_-)\| &= \langle \theta^{-1}(\omega)|\Omega, \Omega \rangle = \langle \theta^{-1}(\omega)p\Omega, \Omega \rangle \\ &\leq |\langle \theta^{-1}(\omega)\pi(a)\Omega, \Omega \rangle| + \varepsilon \leq \|\omega\| + \varepsilon \end{aligned}$$

shows that the positive part ω_+ in the Jordan decomposition of ω is given by the functional calculus $\omega_+ = \theta(\theta^{-1}(\omega)_+)$ by the ramp function. Moreover, every monotone function can behave like an operator monotone function on a commutative C^* -algebra, so we can deduce $\omega_+ \leq \omega'_+$ if $\omega \leq \omega'$ in A^{*sa} .

Now we prove the theorem. Define

$$G^* := \left\{ \omega \in \overline{F^* - A^{*+}} : \begin{array}{l} \text{there is a bounded net } \omega_i \in F^* - A^{*+} \\ \text{such that } \omega_i \rightarrow \omega \text{ weakly}^* \text{ in } A^* \end{array} \right\}.$$

It suffices to show $F^* - A^{*+} \subset G^*$, $G^{*+} \subset F^*$, and $\overline{G^*} \subset G^*$. We can easily check $F^* - A^{*+} \subset G^*$ by considering constant sequences.

If $\omega \in G^{*+}$, then there exist a bounded net $\omega_i \in F^* - A^{*+}$ and a net $\varphi_i \in F^*$ such that $\omega_i \leq \varphi_i$ for all i and $\omega_i \rightarrow \omega$ weakly* in A^* by definition of G^* . Since $0 \leq \omega_{i+} \leq \varphi_i \in F^*$ implies $\omega_{i+} \in F^*$, and since the net ω_{i+} is bounded so that we may assume $\omega_{i+} \rightarrow \omega'$ weakly* in A^* , we have $0 \leq \omega \leq \omega' \in F^*$, whence $\omega \in F^*$.

To show G^* is weakly* closed, take a bounded net $\omega_i \in G^*$ in the spirit of the Krein-Šmulian theorem such that $\omega_i \rightarrow \omega$ weakly* in A^* . Then, for each i we have a bounded net $\omega_{ij} \in F^* - A^{*+}$ and a net $\varphi_{ij} \in F^*$ such that $\omega_{ij} \leq \varphi_{ij}$ for all j and $\omega_{ij} \rightarrow \omega_i$ weakly* in A^* by definition of G^* . Note that $\omega_{ij} \leq \varphi_{ij}$ implies $0 \leq \omega_{ij+} \leq \varphi_{ij} \in F^*$, and $\omega_{ij+} \in F^*$ is a bounded net for each i so that we may assume $\omega_{ij+} \rightarrow \omega'_i$ weakly* in A^* with $\omega'_i \in F^*$. Again, $\omega_i \leq \omega'_i$ implies $0 \leq \omega_{i+} \leq \omega'_i \in F^*$, and $\omega_{i+} \in F^*$ is a bounded net so that we may assume $\omega_{i+} \rightarrow \omega'$ weakly* in A^* with $\omega' \in F^*$. Then, $\omega \leq \omega' \in F^*$ implies that $\omega \in F^* - A^{*+} \subset G^*$. \square

ACKNOWLEDGMENTS

The author is grateful to his advisor Yasuyuki Kawahigashi for his enormous support and encouragement during the master's studies. The author would also like to thank Narutaka Ozawa for his fruitful comments, particularly pointing out a mistake of the author in the original version, and for extremely valuable suggestions on a simpler proof than the complicated original proof. Finally the author thanks Hikaru Awazu and Ayoub Hafid for helpful discussions.
